© 2013 MTL Instruments Group plc. All rights reserved.

INM7700-8 September 2013
The following MTL7700 Series Shunt Diode Safety Barrier Assemblies were submitted to the Mine Safety and Health Administration (MSHA) of the U.S. Department of Labor for acceptance as part of an MSHA approved permissible system or machine.

MTL7715+   MTL7715P+   MTL7755ac
MTL7760ac   MTL7761ac   MTL7765ac
MTL7766Pac  MTL7767+   MTL7787+/-

These Safety Barrier Assemblies were evaluated by MHSA and judged to meet the applicable requirements of Title 30 Code of Federal Regulations, Part 18.68 (30 CFR Part 18.68) provided that a relevant installation complies with the following conditions.

• a) The installation shall preclude intermingling between intrinsically safe circuits, including their associated wires and cables, and all other circuits, wires, and cables.
  
  • b) The MTL7700 Series Shunt Diode Safety Barrier Assemblies must be securely mounted within a suitable dust-tight enclosure in a fresh air area of the mine or an explosion-proof enclosure.
  
  • c) The MTL7700 Series Shunt Diode Safety Barrier Assemblies must be grounded according to the manufacturer’s instructions.
  
  • d) The equipment connected to the input terminals of the barrier must not use or generate more than the maximum 120Vrms.
1 OVERVIEW

This instruction manual contains all information needed to install, maintain, fault-find and test MTL7700 Series shunt-diode safety barriers.

Section 3 includes a checklist of essential safety factors that must be considered when using MTL7700 Series barriers as intrinsically safe (IS) interfaces between safe and hazardous areas. Read section 3 before beginning installation. Users within the European Community should also refer to the supplied MTL publication: INA7700 MTL7700 Series Instructions for Safe Use

It is assumed that all necessary system design, specification and engineering factors have been taken into account BEFORE installation work begins. To assist pre-planning, the following MTL publications covering the theory, design, application, specifications and certification of shunt-diode safety barriers are available:

AN9003 Application Note: A user’s guide to intrinsic safety
AN9007 Application Note: A user’s guide to MTL700 Series shunt-diode safety barriers
MTL IS catalogue The MTL IS catalogue includes detailed specifications of all MTL7700 Series barriers and accessories
IS certificates Copies of Baseefa, FM and CSA IS apparatus and system certificates for MTL7700 Series barriers

If not supplied with the product, these publications are available either from the company website (www.mtl-inst.com) or on request from your local MTL office.

2 DESCRIPTION

2.1 Introduction

MTL7700 Series ‘fourth-generation’ intrinsically safe shunt-diode safety barriers are innovative successors to the MTL700 Series. MTL7700 Series barriers are 1-, 2- or 3-channel devices that use intrinsically safe explosion-protection techniques to pass electrical signals between safe and hazardous areas, whilst limiting transferred energy to a level that cannot ignite flammable atmospheres.

Connected in series with wiring entering any hazardous area on process plant, MTL7700 Series barriers prevent explosions in all normally occurring explosive atmospheres – including mixtures of air with flammable gases, vapours, dusts and fibres – if a fault or faults develop in the safe area.

2.2 MTL7700 Series – barrier ranges

The range is based on a choice of models which, between them, cover virtually all applications – including the protection of installations incorporating uncertified devices known as ‘simple apparatus’ (eg, switches, thermocouples, resistive sensors, photocells and LEDs) or separately certified ‘energy-storing’ or ‘voltage-producing apparatus’ (eg, ac sensors, proximity detectors, transmitters and current-to pneumatic (I/P) converters. Being intrinsically safe, shunt-diode barriers enable maintenance work or calibration to be carried out ‘live’ without additional precautions. To simplify selection, several ‘key’ barriers (see table 1) are highlighted as meeting the majority of process control requirements.
2.3 MTL7700 Series – accessories

MTL7700 Series barriers mount directly onto DIN-rail. A comprehensive selection of mounting, tagging, power and earthing accessories is available. Installation details are given in section 4.3.

Essential accessories

The following are usually considered essential for mounting and earthing MTL7700 Series barriers:

- DIN-rail (e.g., THR2 or THR7000)
- Insulating spacers (e.g., ISP7000)
- Earth terminal (e.g., ETL7000)

The tagging systems for individual modules and columns of barriers are described here. They are shown below under Tagging accessories for columns of barriers.

### Mounting accessories (figure 2)

- **THR2**: Standard DIN-rail, 35 x 7.5mm, (in 1m lengths)
- **THR7000**: Nickel-plated DIN-rail, 35 x 7.5mm, for use in potentially corrosive atmospheres (in 1m lengths)
- **ISP7000**: Insulating spacer: attaches to the base of a DIN-rail to isolate the IS earth from a structural earth

### Tagging accessories for individual barriers (figure 2)

- **TH7700**: Tag holder for mounting on the top of an individual barrier

### Tagging accessories for columns of barriers (figure 2)

- **TAG57**: Tagging strips for mounting over a column of barriers, for marking barrier locations. Supplied (with labels) in 1m lengths for cutting to size.
- **TGL7700**: Spare labels for use with TAG57 tagging strips: 0.5m strips, supplied in sets of 10.
- **IMB57**: Tagging strip supports. Two needed for each tagging strip. It can also be used as centre support by breaking off the top end tab.

### Power accessories (figure 3)

- **BPL7700**: Power link for feeding 24V dc to a maximum of 40 barriers in a single column from an MTL7798 power feed module or MTL7799 Dummy module.

### Earthing accessories (figure 3)

- **ETL7000**: Earth terminal providing connections for routeing the IS earth from the DIN-rail to an appropriate plant earth. Two recommended for each length of DIN-rail.

---

**Figure 2: MTL7700 Series mounting and tagging accessories**
Figure 3: MTL7700 Series earthing accessories

Note: Module earth terminals may be used for cable screen earth connections. See Figure 17

ERB57S Nickel-plated straight earth-rail bracket, supplied with two push fasteners, one 14mm earth-rail clamp and one 9mm earth clamp < 16mm².

ERB57O Nickel-plated offset earth-rail bracket, supplied with two push fasteners, one 14mm earth-rail clamp and one 9mm earth clamp < 16mm².

ERL7 Nickel-plated 3 x 10mm earth rail supplied in 1m lengths. Provides earthing facilities for cable screens and 0V earth returns, additional to those provided on the module earth foot.

ETM7 Earth terminal (5mm wide) for attachment to an ERL7 earth rail, for terminating cable screens and spare cable cores.

3 SAFETY CONSIDERATIONS

3.1 General requirements

All installers of shunt-diode barriers should be familiar with the installation instructions provided by nationally accepted codes of practice, eg, BS EN 60079-14 for the UK, or a recommended practice, eg, ANSI/ISA-RP 12.6 for the USA.

Users within the European Community should also refer to the supplied MTL publication:

INA7700 MTL7700 Series Instructions for Safe Use

3.2 Safety checks

Table 2 itemises the essential checks that should be carried out to ensure the safety of a barrier installation. Use the checklist to prevent important safety considerations being overlooked when installing, commissioning, modifying or servicing an installation of MTL7700 Series barriers. Check the list both before and after a barrier system has been installed, the final check being made by someone other than the person(s) who carried out the installation work. Each item in the list is cross-referenced to the appropriate section of the manual.

For Factory Mutual (FM) based installations see FM certification information.

4 INSTALLATION

4.1 General

MTL7700 Series barriers clamp directly onto standard T-section DIN-rail (DIN EN 50 022). The simple mounting procedure for barriers is described in section 4.2 and for accessories in section 4.3.

4.1.1 DIN-rail length

BEFORE mounting the barriers, make sure the rail length is sufficient for the proposed number of barriers and for other mounting accessories. As a guide, on a given length of DIN-rail, allow space (length) for:

a) Barrier packing pitch: 12.6mm
b) ETL7000 earth terminals: 10mm each (minimum of two)
c) IMB57 tagging strip support (if specified)
16.0mm (minimum of two)
d) ISP7000 insulating spacer (if specified)
14.7mm (minimum of two)*
e) ERB57S or O earth-rail mounting bracket (if specified)
8 mm (minimum of two)

* See Note in section 4.3.2

Make sure that there is sufficient clearance between the DIN-rail and any possible obstruction (eg, other columns of barriers) to remove barriers and install accessories such as ERB57S/O earth rails.

Provide sufficient height for IMB57 tagging strip supports and ISP7000 insulating spacers when fitted.

As a guide, refer to figure 4 (dimensions of an individual barrier) and figure 5 (clearances needed for accessories).

4.2 Mounting/removing barriers

MTL7700 Series barriers clamp directly onto T-section DIN-rail, earthing the barrier through the rail.

a) Hook the hazardous-area end of the mounting/earthing clamp over the hazardous-area flange of the DIN-rail (figure 6).

b) Push the safe-area end of the barrier firmly down by hand until it clicks into place.

c) Check that the barrier is securely clamped into place (see notes below).

d) To remove a barrier (figure 7), use the tip of a screwdriver (with a blade width of 4 to 5mm, minimum shaft length 60mm) to ease the metal clip at the base on the safe-area end outwards until the barrier is freed and can be removed easily by unhooking the hazardous-area end.

Notes

1: Make sure the barrier is properly clamped onto the rail to ensure the essential earth connection. In a row of barriers, one end of an improperly mounted barrier will stick up slightly.

2: Once an MTL7700 Series barrier is fitted, its mounting/earthing foot grips the DIN-rail strongly in order to maintain positional stability and create a high-integrity earth bond. The unit should not be forced along the rail. If it is necessary to reposition a barrier, detach it from the DIN-rail and re-attach it in the correct location. Where minor repositioning is needed, relieve the pressure on the spring of the mounting foot with a screwdriver and ease the unit into place.

4.3 Installing accessories

See section 2.3, figure 2 and figure 3 for brief details of the accessories available for use with MTL7700 Series barriers. More information and installation details (where relevant) for the various accessories are detailed in the following sections:

Mounting accessories Section 4.3.1 to 4.3.

**Figure 4:** Dimensions (mm) of an MTL7700 Series barrier

**Tagging accessories**  Section 4.3.5, 4.3.6

**Power links**  Section 4.3.7, 4.3.8

### 4.3.1 DIN-rail (THR2 and THR7000)

MTL can supply both standard (THR2) and plated (THR7000) low-profile T-section DIN-rail. Although standard DIN-rail maintains a high-integrity earth in normal conditions, for aggressive environments MTL provides THR7000 nickel-plated DIN-rail. Both types are supplied in 1m lengths for cutting to size as necessary. Although there is no strict requirement for the DIN-rail to be isolated from earthed surfaces, it is advisable, in order to minimise the possibility of the earth circuit being invaded by fault currents which might interact adversely with other systems. ISP7000 insulating spacers are a convenient method of insulating the DIN-rail. It is much easier to install insulating spacers during the initial build, than to discover later that an equipped and running installation must be modified.

### 4.3.2 Insulating spacers (ISP7000)

When used, ISP7000 insulating spacers are attached to each end of the DIN-rail and at intervals depending upon the length of the rail. It is recommended that spacers be mounted at 300mm intervals on low-profile (7.5mm) DIN-rail and at 500mm intervals on high-profile (15mm) rails – see figure 8. The spacers are provided with suitable screws for attaching to both the DIN-rail and the mounting surface, which will need to be suitably drilled and tapped for the purpose.

Install each spacer as follows (figure 9):

- a) On the mounting surface, drill and tap two holes for M4 screws.
- b) Attach the spacer to the surface with the two M4 x 16 screws provided.
- c) Drill an M6 clearance hole (6.5mm) in the centre of the base of the DIN-rail (if not already suitably slotted).
- d) Attach the DIN-rail to the spacer with the M6 x 16 screws provided.
4.3.3 DIN-rail earth terminal (ETL7000)

See figure 10. For those applications (the majority) in which the IS earth is NOT routed through the mounting surface, connections for routing the IS earth from the DIN-rail to an appropriate plant earth are made through earth terminals (ETL7000) clamped onto the DIN-rail. Two terminals are recommended, one at either end of a column of barriers, to provide redundancy and to simplify earth testing procedures.

**WARNING:** Apart from rare occasions when the mounting surface carries the IS earth, the ONLY method of providing the IS earth connection from any one column of MTL7700 Series barriers is from ETL7000 earth terminals. Never make the plant IS earth connection to the earth screen on any individual barrier: this is MANDATORY. See also section 5.3.

ETL7000 terminals are attached to the rail as follows. Ensure the same security of the earth connection to the rail as for the barriers themselves (see section 4.2):

- a) Hook the fixed end-clamp of the terminal over one flange of the DIN-rail.
- b) Press the body of the terminal downwards until the pivoting end-clamp engages the other flange of the DIN-rail.
- c) Clamp the terminal firmly into place by tightening the centre screw.
- d) Important: wire up the earth terminal as given in section 5.3.2.
4.3.4 Earth rail assembly (ERL7/ETM7/ERB575/O)

A screw terminals on each barrier is available for terminating cable screens and OV returns. An alternative is provided by an earth rail assembly (figure 12). This consists of two IMB57’s, ERB575 or O, mounting blocks (one for each end of a column of barriers), a length of ERL7 earth rail (supplied in 1m lengths for cutting to size), and ETM7 terminals for connecting cable screens or OV returns to the rail.

Install the earth rail assembly as follows:

a) Hook the loose end-clamps of the IMB57 mounting blocks over the flanges of the DIN-rail at each end of the row of barriers.
b) Making sure the blocks are flush with the end barriers or tagging strip supports, clamp them firmly into place by tightening the screws at the base of the blocks and fit 2 off ERB575 or S into supports.
c) Slide the number of ETM7 terminals required for connections onto the length of ERL7 rail needed for the assembly.
d) Important: wire up the earth rail assembly as given in section 5.3.3.

4.3.5 Barrier identifiers (TH7700)

TH7700 tag holders (figure 11) are clipped onto the tops of individual barriers to provide transparent holders for identification labels.

a) Slide the required label in between the top and lower parts of the TH7700.
b) Push the tag holder downwards until it clips into place.
c) To unclip a tag holder, lever up the far end above terminals.

Note: Early versions of TH7700 are hinged on two small locating pins. Later versions are hinged by locating the clips at the hinged end into the rectangular appurtenances on the barrier body. The later design can be retrofitted on early modules by removing the hinge pins with a knife.

4.3.6 Tagging strip assemblies (IMB57)

The tagging strip assembly (figure 12) identifies the location of individual barriers, ensuring that they are replaced correctly after removal for maintenance or testing. Once installed, the tagging strip pivots upwards to provide access to, and allow removal of, individual barriers.

Each assembly uses two tagging strip supports (IMB57), a tagging strip (TAG57) and tag labels (TGL7700).

The assembly installation procedure is:

a) IMB57 tagging strip support. Making sure that the vertical slots are on the hazardous-area side, hook the loose end-clamps of each IMB57 tagging strip support over the flanges of the DIN-rail at each end of the group of barriers.
b) Make sure that the tagging strip support is flush with the end barrier in the row.

IMB57 tagging strip support. Clamp firmly in place by tightening the two screws located at the foot of each support.
c) Remove any clic rivets from the tagging strip and slide out the label.
d) Measure the distance between the top inside faces of the two tagging strip supports.
e) Cut the tagging strip and label to this length with a hacksaw.
f) Annotate the tagging strip label as required and slide it back into the tagging strip. Divisions on label strips are 12.6mm wide, the pitch of individual barriers.
g) Clip the tagging strip onto the lugs on top of the tagging strip supports.

4.3.7 Power bus (BPL7700)

For details on using and installing a power bus, see section 5.2.3.
5 WIRING CONNECTIONS

5.1 General
This section describes wiring connections as follows:

a) Barrier connections Section 5.2
b) Connections to plant earth Section 5.3
c) Connections to dummy barriers Section 5.4

5.2 Barrier connections
Each barrier has 4 or 8 terminals, 2 or 4 on each side, allocated as follows:

Safe area
Terminals 1, 2, 5 and 6 Safe-area power and signal lines Sections 5.2.1 and 5.2.2

Hazardous area
Terminals 3, 4, 7 and 8 Hazardous-area signal lines Section 5.2.1

Torque the screw terminals to 0.4Nm.

5.2.1 Signal line connections
Connect signal lines to the screw terminals at both sides of the barrier (1 and 2 and/or 5 and 6 at the safe-area side, 3 and 4 and/or 7 and 8 at the hazardous-area side). The safe-area terminal 1 is also used as a power connection when power is provided from the safe area (see section 5.2.2 for details).

Clearly segregate hazardous-area and safe-area cabling as defined by relevant codes of practice, and route cabling to the barriers through clearly separated and identified conduits or trunking. Deal with spare cable cores or screens as described in section 5.2.3.

Before making any signal connections from the hazardous area, make sure any energy-storing devices (ie, devices NOT classified as ‘simple apparatus’) are certified as being compatible with the barriers to which they will be connected. Check also that the connecting cables conform with the cable types specified by the safety documentation and that the maximum cable parameters specified in MTL’s IS catalogue are not exceeded. In general, cable parameters are unlikely to present problems except in installations where cables longer than 500m are called for in IIC applications.

Do not connect barriers to safe-area equipment that is supplied from (or contains) a source of potential with respect to earth that is greater than 250V rms or 250V dc under normal or fault conditions, unless this is specifically permitted by the safety documentation. This limitation does not apply to safe-area equipment fed by a three-phase 440V neutral earth supply.

See Appendix A for examples of wiring connections for specific applications.

5.2.2 Power supply connections general considerations
Take care that if barriers are connected to a safe-area power supply, connections are made correctly. If the internal safety fuse blows, it will destroy MTL7700 barriers. See Appendix A for specific connections for individual barriers and applications.

5.2.3 Bussed Power applications and connections
When a number of barriers use a common power supply, the optional power link (BPL7700) can be used. Typical applications include hazardous-area switches, solenoids and 4–20mA transmitters; and the barriers it can be used with are the MTL7706, MTL7707+, MTL7787+, MTL7787P+ and MTL774x. See figure 14 for a typical power link installation applied to hazardous-area switches.

Up to 40 barriers can be linked using the power links. The link itself is supplied from a power feed module (MTL7798). The MTL7798 power feed module is provided with a trip circuit which protects the barriers by switching off their supply if a fault (such as an overvoltage) occurs in the power source. The state of the module is indicated by one of two LED indicators:

a) Green ON when supply is normal and being passed to the barriers.
b) Red ON when the trip mechanism is activated indicating a fault.

After a fault has been indicated, the module can be reset by disconnecting the main power supply.

Install the power links as follows (figure 13):

a) Mount an MTL7798 power feed module on the DIN-rail at one end of the column of barriers being supplied.
b) Connect a safe-area 20–26V dc supply to terminals 5 and 6 of the power feed module.
c) Select the number of links required.
d) Lift the tag holders to gain access to the power link connectors and insert the links (figure 13).
e) Close the tag holders.
f) To replace the barrier, lift the identifiers either side of the appropriate barrier to check which one is linked, remove the link, replace the barrier and re-insert the link and close the identifiers.

WARNING
Do not remove bussed power links with power applied if installed in FM Div 2 / ATEX Zone 2

5.2.4 Spare cores/screens/0V returns: connections
Unused cores should be connected to 0V. Terminals on the earth foot simplify this.

5.3 Connections to plant earth

5.3.1 General considerations
A barrier installation must be earthed properly for correct and safe operation. Care must be taken that individual barriers are correctly mounted so that the earth connection with the DIN-rail is secure.

An installation must, in turn, be connected to a suitable plant high-integrity earth. This should be done by connecting suitable conductors to ETL7000 earth terminals (see section 5.3.2). It is also usually advisable to make sure that the DIN-rail is isolated from any possible enclosure earths by separating it from the mounting surface with ISP7000 isolating spacers (see section 4.3.2).

See Appendix A for examples of wiring connections for specific applications.

Figure 13: Power link installation
5.3.2 Earthing an installation

See figure 15. Connections from the DIN-rail to a suitable plant earth are made from ETL7000 earth terminals. These clip onto the DIN-rail as described in section 4.3.3 to make the vital earth connection with the rail and the barriers. They are provided with two screw-clamp terminals, to one of which a copper conductor to plant earth should be connected. This should have a resistance no greater than $1\,\Omega$ though to increase safety and reduce interference, a resistance as close to $0.1\,\Omega$ as possible is preferable. The cross-sectional area of the conductor should be as least $4\,\text{mm}^2$ (12 AWG).

It is advisable to mount one ETL7000 earth terminal at each end of a column of barriers to provide redundancy by connecting both ETL7000 terminals to the plant earth. This makes it possible to introduce a multimeter into one of the loops to measure loop resistance without breaking the earth connection (figure 16) – a test which should be done periodically. In these circumstances, resistance for each cable loop should not exceed $2\,\Omega$.

The IS plant earth conductors should be clearly identified to warn against unauthorised interference. Though not mandatory, it is recommended that this should be done by winding blue insulating tape round the conductors at intervals along their length.

**WARNING**

Do not use earth foot terminal as an IS earth termination. Make IS earth connections using an ETL7000 earth terminal as described in section 5.3.2.
5.3.5 Bonding practice when hazardous-area equipment cannot meet prescribed insulation standards

Where hazardous-area equipment is connected to earth (either directly or indirectly) and/or it will not withstand a 500V insulation test to ground or the alternative described in section 5.3.4, eg, strain-gauge bridges with low-voltage insulation, pH and conductivity sensors, bare and/or earthed thermocouples, and some level detectors, the following considerations apply:

Safety considerations

a) The pipe, vessel, or body of the hazardous-area apparatus and/or the adjacent metallic structure must be connected to the barrier DIN-rail [see item d)] by a bonding conductor of at least 4mm² cross-sectional area for lengths of 100m or less; or at least 8mm² area for lengths between 100m and 200m.

b) Where bonding conductors are used, care must be taken to avoid invading other intrinsically safe systems (those not using bonding conductors) by elevation arising from currents which may flow in the common earthing systems as a result of the presence of the bonding conductor. Where this possibility cannot be avoided, then barriers associated with bonded systems should be mounted on a separate DIN-rail from those on which other barriers are mounted. Additionally, the DIN-rails themselves should also be earthed separately.

c) The hazardous-area equipment and/or adjacent metallic structure bond connections must be secured against vibration and corrosion. A terminal of the type used on ‘increased safety’ (‘e’) equipment is the mandatory solution.

d) The barrier DIN-rail connections must provide suitable termination facilities for the bonding conductor and usual ‘earth return’ by being equipped with separate increased safety (‘e’) terminals.

Operational requirements

e) Figure 18 shows the OV rail of the safe-area equipment returned to the barrier DIN-rail by a separate insulated conductor and the structural earths of any safe-area equipment returned separately to the neutral star-point. This reduces interference problems but is not essential for safety reasons.

f) In general, the use of barriers in all measurement leads reduces the possibility of earth circulating currents causing measurement problems.

g) Resistance from the neutral star point to ‘terrestrial earth’ – via the buried earth mat or rods – is determined by other regulations and is not modified or determined by the intrinsic safety requirements, which are concerned with the plant earth only.

5.4 Connections to dummy barriers

See figure 19. The MTL7799 dummy barriers provide safe connection facilities for unused cable cores, cable screens and OV returns. In addition, safe-area terminals 2 and 1 are connected internally to provide a straight ‘feedthrough’ 24V dc supply connection, enabling the units to be used as feed modules for use with a power bus, useful in applications where the fault trip mechanism of the MTL7798 is not needed.

6 MAINTENANCE

6.1 General

Circuits in all MTL7700 Series barriers are encapsulated and so cannot be repaired. However, provided they are correctly installed and connected (as described in sections 4 and 5 of this manual) and the circuits they protect are not themselves defective, barrier faults are highly unlikely to occur. Therefore, servicing of barrier installations consists mainly of routine inspection and earth testing as described in this section.

More information about the maintenance of barrier installations is given in BS EN 60079-17.

6.2 Routine inspection

At intervals not exceeding two years (more frequently for harsh environments), make a visual check of the barrier installation. Personnel undertaking these checks should comply with all regulations relating to the safety of plant and personnel. Care must be taken to prevent any inadvertent direct connection between hazardous- and safe-area circuits and, at all times, the safety precautions discussed in section 3 MUST be observed.
Check that:

a) Barriers are of the types and polarities specified in the safety documentation.

b) The barriers are attached securely and correctly to the DIN-rail to make sure the earth connection is safe.

c) There are no apparent signs of damage or corrosion to the barriers, the ETL7000 earth terminals, the plant earth connections, and, if fitted, any earth rail assemblies.

d) All hazardous-area and safe-area cable connections are made correctly and the terminals properly tightened.

e) Interconnecting cables are of the type and rating specified by the safety documentation and that they are not frayed or otherwise damaged.

f) All earth returns and cable screens from the hazardous area are connected to earth either through a barrier, a dummy barrier or an earth rail.

g) Visually examine the earth conductors and make sure they are not damaged in any way and that their terminations are secure and free from corrosion.

h) Using a low-voltage low-current test meter (ie, a meter with an output not exceeding 3V and 50mA), measure the resistance between the DIN-rail and the neutral star-point of the supply and make sure it does not exceed 1Ω. Record the reading and compare it with readings taken during previous inspections. A consistent reading repeated over a long period of time is a reassuring sign indicating a sound earth return which is likely to remain so. If two earth conductors are used as described in section 5.3.2, the loop resistance should be measured as described in that section and the reading should not be greater than 2Ω.

**WARNING:** do not try to carry out a high-current earth resistance test unless it is confirmed by the authority in charge of the plant that the plant is gas-free.

---

**7 FAULT-FINDING**

**7.1 Introduction**

Most barrier-protected systems are relatively simple and their operation is easy to check. However, when fault finding is necessary, it must only be undertaken after checking with plant personnel responsible for safety that it is safe to proceed.

The fault-finding procedures described in this section call for the use of a digital multimeter – this being the most common type used. However, other types can be used provided their characteristics when measuring silicon diodes are known.

Many digital multimeters include a diode test function which is useful when diode chains are included in the test. These usually operate by passing 1mA through the diode and measuring the voltage across it. When measuring more than two diode drops in series, note that the full-scale range of some multimeters is only 2V on the diode test range. With three or more diode drops it is therefore possible that the meter may indicate over-range. In the test tables (tables 4 to 10), any drop of more than 4V is indicated as infinity (∞).

Zener diodes and ordinary silicon diodes have a typical forward voltage drop of approximately 0.6V/diode. Diode return paths with Schottky diodes have a typical voltage drop of <0.3V for each diode in the chain, eg, MTL7787+, 7787P+.

Figure 20 depicts a typical switch-status transfer circuit protected by an MTL7787+ barrier which illustrates some of the fault-finding techniques discussed in this section. To determine the serviceability of MTL7700 Series barriers, follow the steps described in sections 7.2 to 7.3.
7.2 Power supply check

Check that the power supply to an individual barrier circuit (or to an MTL7798 power feed module or an MTL7799 dummy barrier sourcing the power bus) is functional and that the voltage across the supply with respect to earth is correct. For example, in Figure 20 the presence of 24V on terminal 1 and 12V on terminal 2 when the switch in the hazardous area is closed confirms the serviceability of almost the complete circuit.

7.3 Barrier resistance test

To test the resistance of a barrier on site, refer to figure 20 and carry out the following procedure:

a) Unplug hazardous-area cables from terminals 3 and 4.

b) Unplug safe-area cables from terminals 1 and 2.

WARNING: Take care when handling safe-area cables; the relay contacts in figure 20 for example could be carrying mains voltage.

c) Measure the end-to-end resistance of the barrier by connecting a digital multimeter (set to a suitable Ω range) between terminals 1 and 3. The reading should typically be slightly less (eg 1–3% lower) than the maximum end-to-end resistance listed in tables 4 to 10 for the appropriate barrier type or approximately 10–20% higher than the figure specified in the safety description.

d) Check the functioning of the diode-return channel (MTL7787+, 7787P+, only) by selecting the diode test function on the multimeter and connecting it between terminals 4 (+ve) and 2 (−ve). This measures the forward voltage drop of the Schottky diodes in the chain: the reading should be less than 0.9V. Repeat the test with the connections reversed (ie, terminals 4 (−ve) and 2 (+ve) for an expected reading of ∞ for the reverse voltage drop.

e) Tests c) and d) confirm the continuity of both barrier channels. If either channel is open-circuit it is most likely that the fuse has blown. The safe-area circuit should be investigated in an attempt to discover the cause of the fault.

Notes: if the barrier is removed, make sure the safe-area and hazardous-area cables disconnected during operations a) and b) are connected to an earth-rail, a dummy barrier or insulated completely.

c) If it is not possible to disconnect wiring to the barrier for steps a) and b), carry out the tests given in table 4.

8 EQUIPMENT AND BARRIER TESTS

8.1 Thermocouple and RTD tests

8.1.1 Thermocouple circuit testing

Thermocouple test and calibration equipment is rarely certified intrinsically safe and therefore requires special authorisation before it can be used for testing or calibrating thermocouple circuits in hazardous areas. To overcome this problem, the thermocouple circuits can be protected by using an MTL7760ac barrier as shown in figure 21. This permits the thermocouple output to be measured without needing special authorisation to use uncertified thermocouple test equipment.

As it is seldom possible to measure accurately the temperatures of thermocouples located in hazardous areas, a safe way of adjusting calibration tables to compensate for plant temperatures is needed. This can be done by disconnecting the compensating cables from the thermocouple, shorting them together, and measuring the temperature of the shorting point.

8.1.2 Resistance temperature detector (RTD) circuit testing

Resistance temperature detector (RTD) circuits can be tested by disconnecting the measuring leads from the RTD head in the hazardous area and connecting them to a resistance box. Sometimes it is more convenient to connect the resistance box in the safe area, for instance at point ‘xx’ in figure 22. For the latter method, however, the RTD must be shorted out or an allowance made for its temperature. The effect of a negative temperature change can be simulated by connecting the resistance box into the measurement lead at point ‘yy’. The advantage of connecting the resistance box at the RTD head is that any leakage can also be determined by connecting the resistance box at point ‘yy’.

8.2 Barrier tests

8.2.1 General

MTL7700 Series barriers do not need to be subjected to routine testing if they are in normal use. Generally, the inspection tests described in section 6 are more than adequate. However, if the performance of barriers is in any way suspect, then carry out the detailed tests described in this section. Barriers which pass these tests satisfactorily are highly unlikely to represent an unacceptable level of risk or cause a circuit malfunction.

There are two types of test (as shown by tables 4 to 10); a simple test using a digital multimeter to test barriers on site and a more comprehensive bench test using a constant current source to establish the breakdown characteristics.

Although certification requirements concentrate on pulse-current tests, in many ways the leakage current tests described in this section are a more satisfactory method of testing suspect diodes. If a complete functional check of a barrier is needed, then the multimeter and constant current tests described in sections 8.2.2 and 8.2.3 should be made although, for most purposes, the multimeter tests should suffice.

8.2.2 Multimeter tests

Figure 20: Switch-status transfer circuit using an MTL7787 barrier

Figure 21: Calibrating a thermocouple barrier circuit
8.2.3 Constant-current tests

Channels.

Isolation tests and for the end-to-end resistance tests for diode return multimeter diode test function is used for the diode tests, channel for diode return channels) and for the continuity tests; and that the range for the end-to-end resistance tests (except set to a suitable Ω is described in section 7. The tables assume that the multimeter is See tables 4 to 10. The use of a digital multimeter for testing barriers and digital multimeters

Figure 22: Calibrating an RTD barrier circuit

See tables 4 to 10. The use of a digital multimeter for testing barriers is described in section 7. The tables assume that the multimeter is set to a suitable Ω range for the end-to-end resistance tests (except for diode return channels) and for the continuity tests; and that the multimeter diode test function is used for the diode tests, channel isolation tests and for the end-to-end resistance tests for diode return channels.

8.3 Tests for Active Barriers

8.3.1 Tests for the MTL7706+

Comprehensive testing requires specialised equipment, beyond the scope of on-site tests. However, an effective test which will confirm that the unit is operating correctly is shown in figure 24. Ammeter 1 measures the transmitter simulator current of between 4 and 20mA flowing from terminal 4 and the safe-area load current flowing to terminal 4 simultaneously. Since these two currents are equal and opposite, the resulting reading on the ammeter should be virtually zero. Ammeter 2 verifies the presence of the 4–20mA transmitter signal.

8.3.2 Tests for the MTL7707+

Since this unit incorporates a built-in protection circuit, it has to be tested in a different manner to an ordinary shunt-diode barrier. Referring to figure 25, set the transmitter simulator to 4mA and to 20mA, and check that the ammeter reads approximately the same value. Then, having set the simulator to 20mA, check that the voltage between terminals 1 and 3 is less than 8.5V and between terminals 2 and 4 is less than 1.6V.

8.4 Test tables for passive barriers

For these tests (last column of tables 4 to 10) a constant-current generator capable of supplying 10µA, 20mA and 40mA currents from a 30V source is needed. Ideally, a purpose-built current generator should be used but, alternatively, a set-up based on a laboratory power supply and two multimeters (figure 23) will serve. The current is measured by one multimeter and trimmed by adjusting the output voltage of the power supply indicated on the second multimeter.

When using a constant-current generator for testing MTL7700 Series barriers, note the following points:

a) The current must be limited to 50mA to avoid damaging the barriers.

b) The accuracy of the current is not critical and can vary by ±5%.

c) Test leads must be connected securely to the barrier terminals; however, the changeover switch and current selector reduce the need for connection changes.

d) Using a high resistance in series with the barrier gives more stable results and makes it easier to set the required current.

Figure 23: Constant-current test circuit using a power supply and digital multimeters

Figure 24: MTL7706+ test circuit

Figure 25: MTL7707+ test circuit
8.3.3 Tests for MTL774x

The MTL774x range are switch/prox input barriers with a choice of changeover relay contacts or a solid state switch acting as the safe area interface. Relay contacts provide a universal interface capable of switching a wide range of signals including ac, low level and high level voltages. Phase reversal is achieved by connecting the normally open or normally closed contacts as required. The solid state switch variants can be configured to switch from a power rail or down to ground and makes these barriers ideal for high switching frequency applications.

When testing bus powered barriers use either an MTL7798 Power Feed module or an MTL7799 dummy barrier for direct 'feed-through' connection of a 24V dc supply.

8.3.3.1 Testing MTL7741 Barriers

The MTL7741 is a single channel switch/prox input barrier with changeover relay contacts acting as the safe area interface. To verify correct operation proceed as follows:

a) Connect the barrier as shown in figure 26.
b) With an ohmeter, check that the output contacts (terminal 5 & 6) close when the input switch is closed.

8.3.3.2 Testing MTL7742 Barriers

The MTL7742 is a single channel switch/prox input barrier with an open collector solid state interface to the safe area equipment. To verify correct operation proceed as follows:

a) Connect the barrier as shown in figure 27.
b) Check that the LED is on when the input switch is closed, and off when the input switch is open.

8.3.3.3 Testing MTL7743 Barriers

The MTL7743 is a dual channel switch/prox input barrier, each channel with a relay interface to the safe area equipment. To verify correct operation proceed as follows:

a) Connect the barrier as shown in figure 28.
b) With an ohmeter, check that the output contacts (terminal 1 & 2) close when the input switch for channel 1 is closed.
c) Repeat the procedure for channel 2.

8.3.3.4 Testing MTL7744 Barriers

This module is a single channel interface for prox/switch inputs with line fault detection. To verify correct operation proceed as follows:

a) Connect the barrier as shown in figure 29.
b) With an ohmeter, check the status of the output contacts according to Table 3

c) Repeat the procedure for channel 2.

8.3.3.5 Testing MTL7745 Barriers

A dual channel version of the MTL7742, this module provides two solid state interfaces for prox/switch inputs. To verify correct operation proceed as follows:

a) Connect the barrier as shown in figure 30.
b) With an ohmeter, check the status of the output contacts according to Table 3
Tables 4 to 10 detail the tests for all MTL7700 Series ‘passive’ barriers. In the ‘diode test’ columns, the figures adjacent to the diode description indicate the number of forward-biased diodes used in the barrier chain. Using the multimeter diode test function and knowing the diode voltage drop figures (approximately 0.6V for each Zener diode and 0.3V for each Schottky diode), the expected reading across the diode chain can be determined.
